

Human Factors in Systems Design

Week Three: Human Information Processing

Module 3 Goals

At the end of this week, students should be able to:

1. Describe a model of Human Information Processing
 2. Describe the function of Signal Detection Theory in classical HFE to include ROC curves
 3. Illustrate and describe the FAA Human Factors model.
 4. Describe the process required to obtain approval from the IRB to conduct human subjects research.
-

This week

Human Information Processing Models, SDT

Wednesday

Turn in Homework (Appendix B Article Critique)

ROC curves

Review of IRB approval for Human Subjects Research

Thursday

Work with team on course project

*“All models are wrong,
but some models are
useful.”*

George Box, 1979

Some Ways to Classify Models

Conceptual _____ Computational

Reductionist _____ First Principled

Static _____ Dynamic

Recursive _____ Non-Recursive

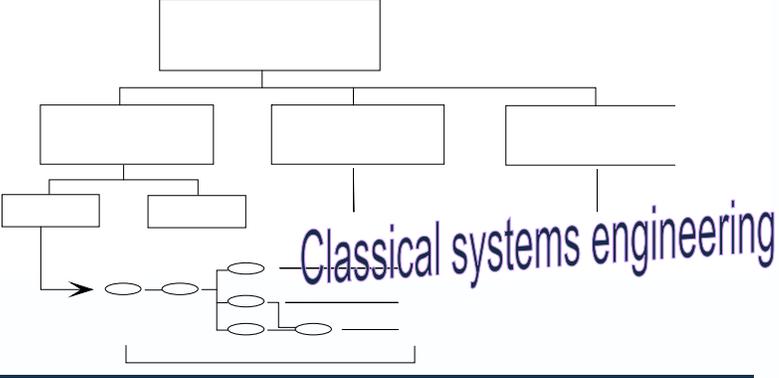

Discrete _____ Continuous

Other ways?

 Two strategies to model human/system performance

Reductionist

- Breaking human activity and interaction with the system into discrete activities

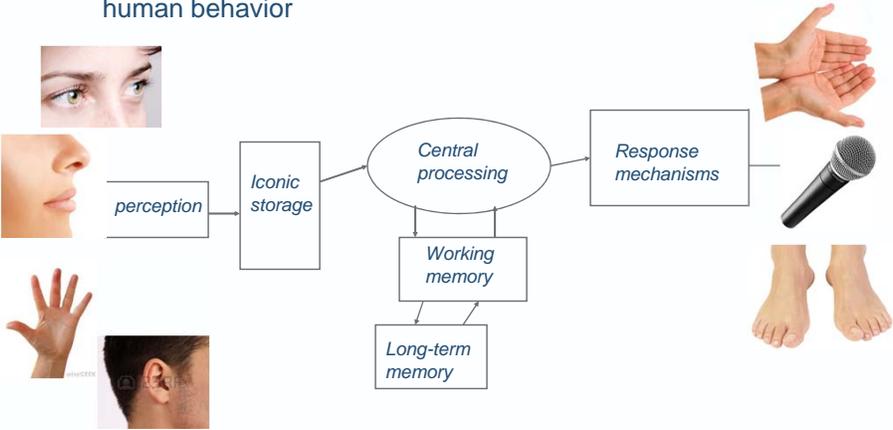

Classical systems engineering

 Two strategies to model human/system performance

First principled

- Based on theories of the underlying mechanisms that facilitate human behavior

perception

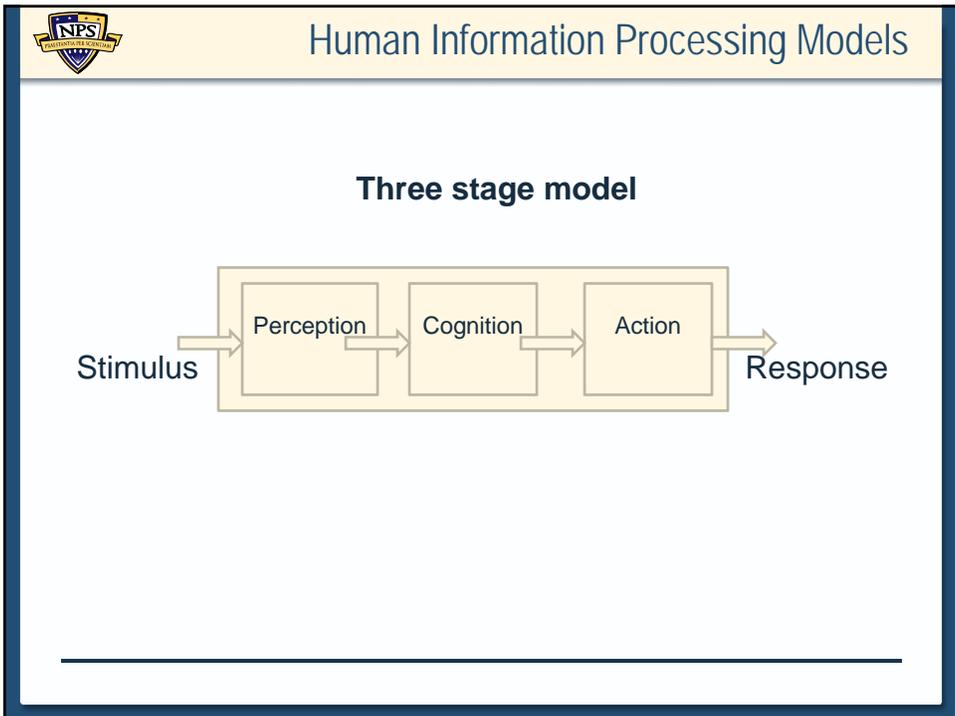

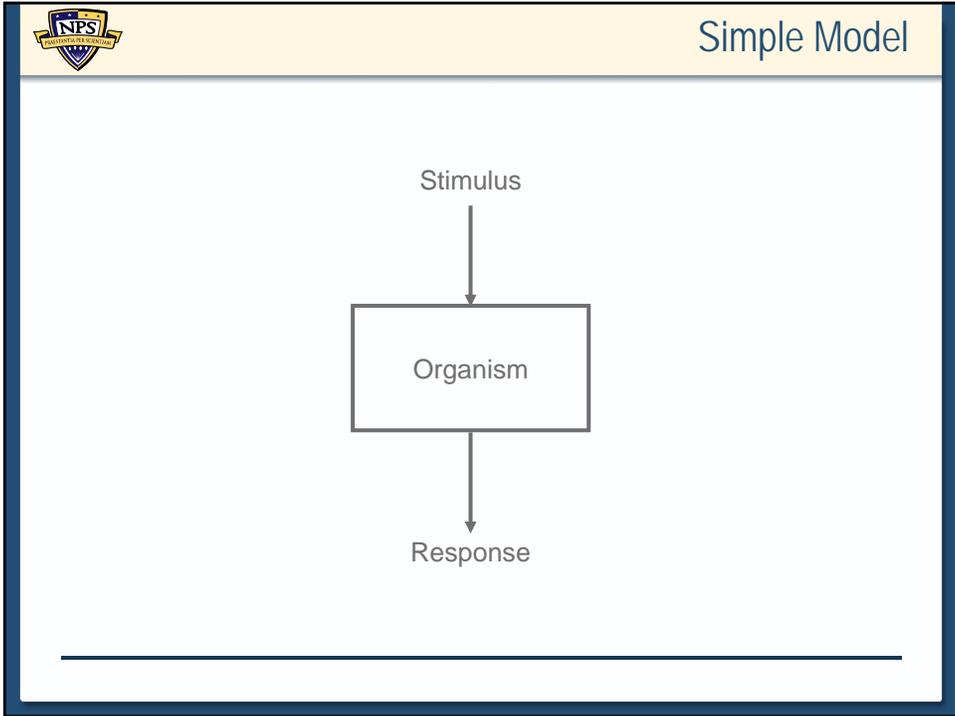

Iconic storage

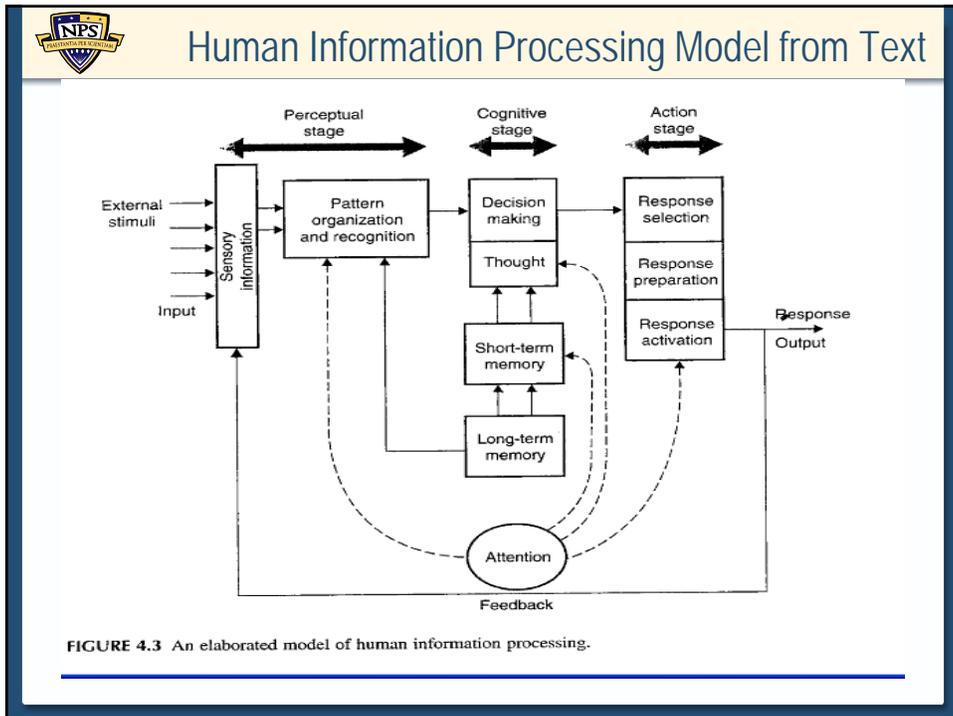

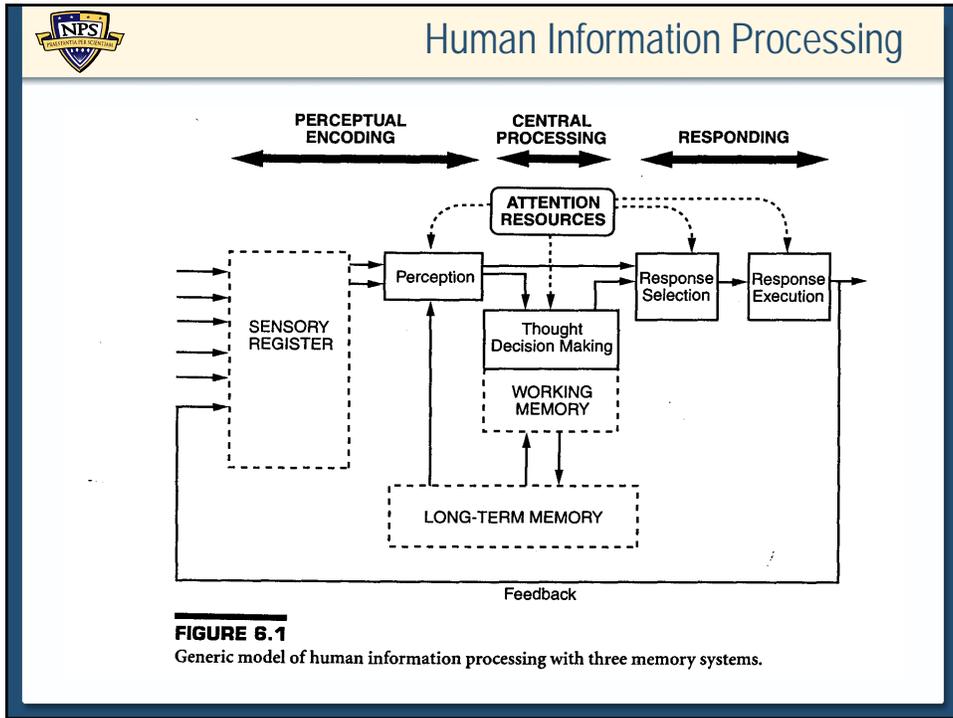

Central processing

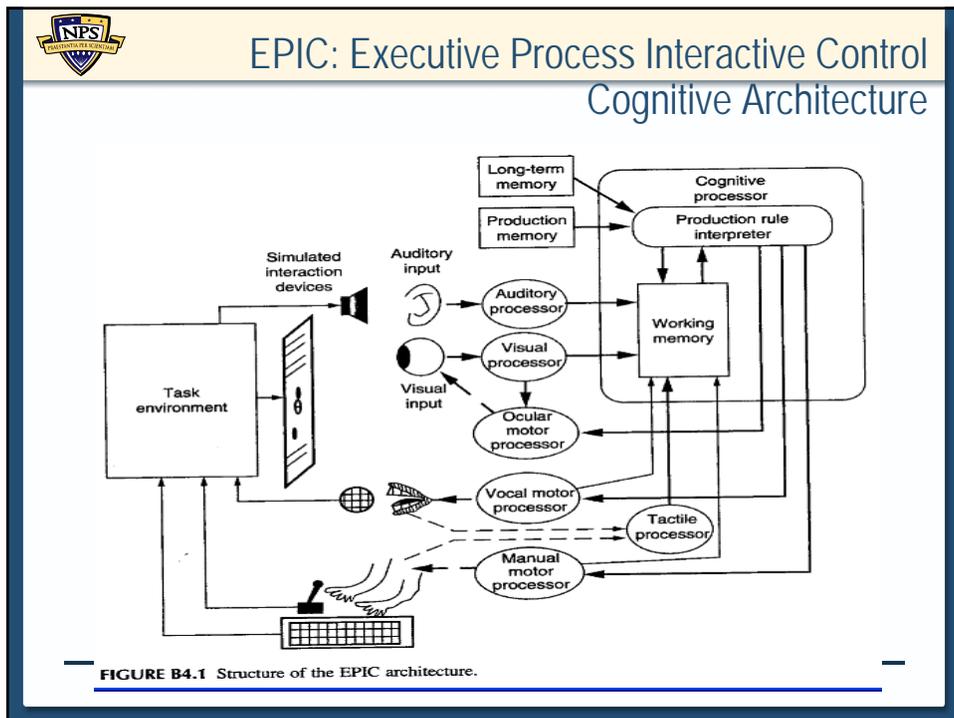

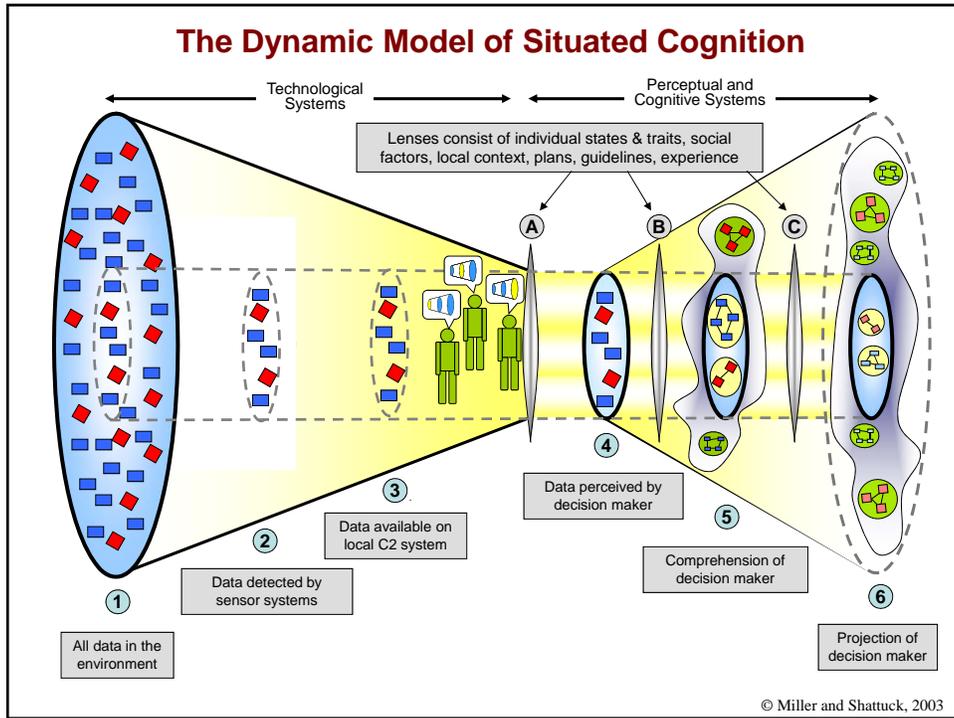

Working memory

Long-term memory

Response mechanisms

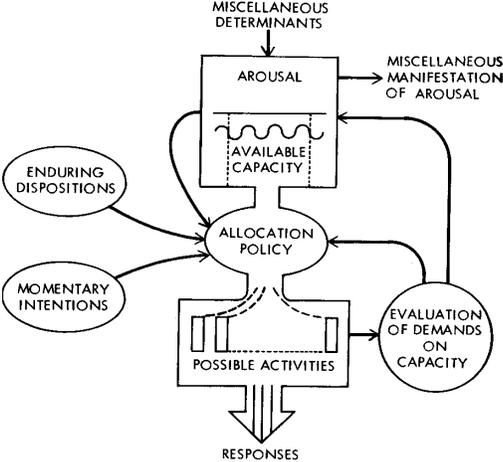

Undifferentiated Attention Model

```
graph TD; MD[MISCELLANEOUS DETERMINANTS] --> A[AROUSAL]; A --> AC[AVAILABLE CAPACITY]; A --> MMA[MISCELLANEOUS MANIFESTATION OF AROUSAL]; AC --> AP((ALLOCATION POLICY)); ED([ENDURING DISPOSITIONS]) --> AP; MI([MOMENTARY INTENTIONS]) --> AP; AP --> PA[POSSIBLE ACTIVITIES]; PA --> R[RESPONSES]; PA --> EDC((EVALUATION OF DEMANDS ON CAPACITY)); EDC --> AP; MMA --> EDC;
```

FIGURE 9-3 Unitary Resource Model of Attention.
From Daniel Kahneman, *Attention and Effort*, © 1973.

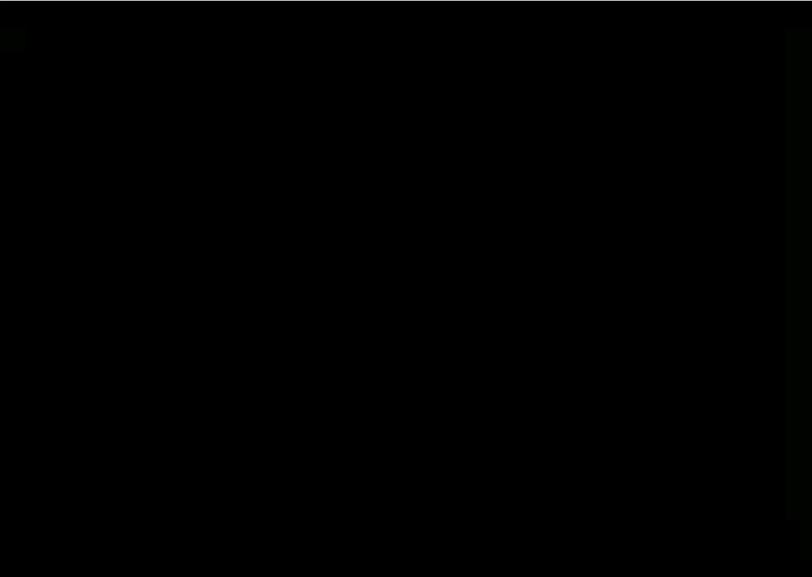

The evaluation of demand is the governor system that causes the capacity to be supplied, as needed by the activities that the allocation policy has selected.

The allocation policy is controlled by 4 factors:

- Enduring Disposition
- Momentary Intentions
- Evaluation of Demands on Capacity
- Effects of Arousal

Just how aware are you? Please view YouTube video: "Test Your Awareness, Do the Test"

Signal Detection Theory

The diagram illustrates the Signal Detection Theory matrix. The vertical axis represents the State of World, with 'Signal Present (+ Noise)' at the top and 'Signal Absent (Noise only)' at the bottom. The horizontal axis represents Operator Behavior, with 'Yes (Signal seen)' on the left and 'No (No signal perceived)' on the right. The four quadrants are: Hit (H) with probability P(H) and a smiley face; False Alarm (FA) with probability P(FA) and a frowny face; Miss (M) with probability 1-P(H) and a frowny face; and Correct Rejection (CR) with probability 1-P(FA) and a smiley face. Dashed lines connect the top-left and bottom-right cells, and the top-right and bottom-left cells. Labels 'Response Bias "Yes" vs. "No"' and 'Sensitivity Low vs. High' are positioned at the bottom of the matrix.

FIGURE 4.10
Representation of the outcomes in signal detection theory. The figure shows how changes in the four joint events within the matrix, influence the primary performance measures of response bias and sensitivity, shown at the bottom.

Is it a signal?

Signal Detection Theory

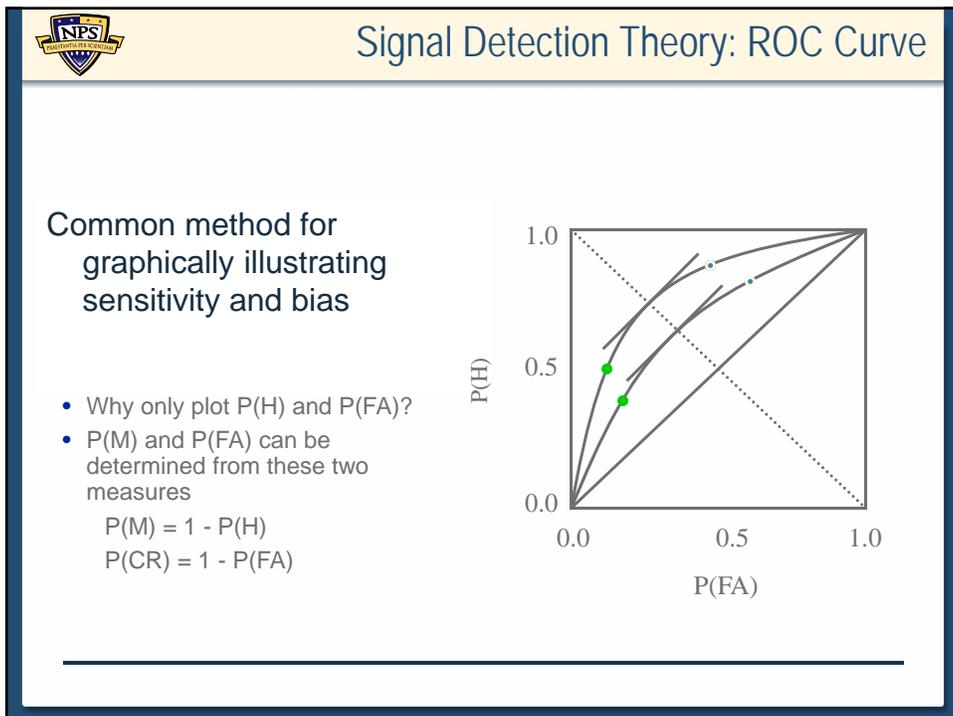

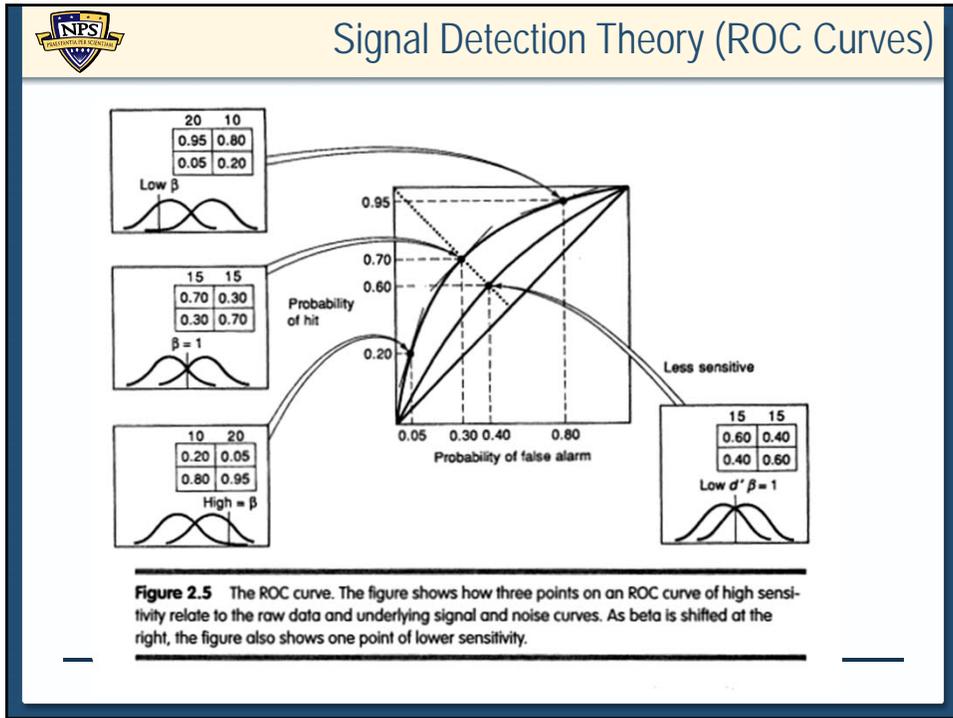

- Response criterion (bias): b
 - Optimal response criterion: b_{opt}
 - Effects of probabilities and payoffs on setting b_{opt}
 - Human performance lags when setting b_{opt} :
termed the '*sluggish beta phenomenon*'
-

Signal Detection Theory

Human detection performance

- Sensitivity
 - d'
 - How good is the operator at the signal detection task?
 - Response bias (beta)
 - Reflects the bias of the operator to respond "yes" versus "no"
 - Top down processing
 - Expectancy that a signal will be seen
 - Changes in the costs and benefits of events can shift the criterion
-

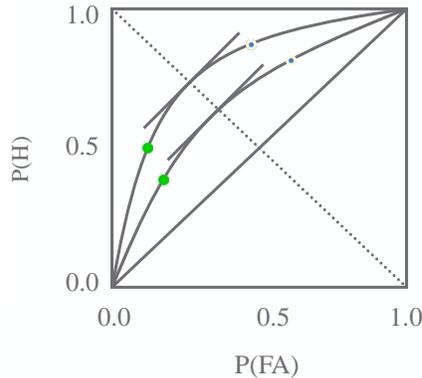

Signal Detection Theory: ROC Curve

What do single points represent?

- particular setting of response criterion at a given sensitivity

How is the “curve” created?

- Vary response criterion (prob. and payoffs) to collect many points

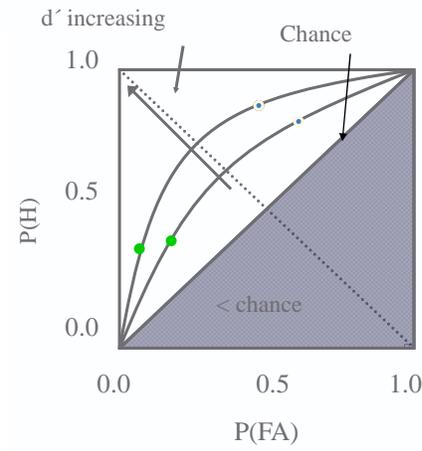

The graph shows a square plot with both axes ranging from 0.0 to 1.0. The vertical axis is labeled P(H) and the horizontal axis is labeled P(FA). A dashed diagonal line from (0,0) to (1,1) represents chance. Several solid curves are plotted above this diagonal line, representing different levels of performance. Two points on one of the curves are highlighted with green dots, and two points on another curve are highlighted with blue dots.

Signal Detection Theory: ROC Curve

Sensitivity (d')

- bow in curve
- computing d'
 - determine P(H) & P(FA)
 - d'

The graph is similar to the one above, but with additional annotations. A shaded triangular region below the diagonal line is labeled "< chance". An arrow points to the upper part of the curves with the label "d' increasing". Another arrow points to the diagonal line with the label "Chance".

Applications of Signal Detection Theory (SDT)

Scientific Psychological Inquiry

- Psychophysics (measuring sensitivity of detection)
- Cognitive Psychology (e.g., recognition memory)

Practical Applications

- Medical Diagnosis
 - Law (eye-witness identifications)
 - Vigilance (sustained attention) tasks
-

Terms for Signal Detection Theory

Response Criterion b (*beta*)

Measures of sensitivity d' (*d prime*)

Applications of SDT

ROC curves

Is it a signal?

Signal Detection Theory

- Response criterion (bias): b
 - Optimal response criterion: b_{opt}
 - Effects of probabilities and payoffs on setting b_{opt}
 - Human performance in setting b_{opt} : *sluggish beta phenomenon*
 - Sensitivity
-

Applications of Signal Detection Theory (SDT)

Practical Applications

- Medical diagnosis
- Law (eye-witness identifications)
- Vigilance (sustained attention) tasks
- Sensor (equipment) design
